ABSTRACT

BACKGROUND

Rheumatoid arthritis is a well-known chronic inflammatory autoimmune disease which affects multiple joints usually in a symmetrical manner. Apart from the joints, RA can affect numerous other systems of the body like cardiovascular, neurological, haematological, skin, blood vessels, etc. The most common cause of death of RA patients has been found to be cardiovascular disease due to coronary artery disease. Chronic inflammatory state and dyslipidaemia^{1,2} have been proposed as the reasons for accelerated atherosclerosis in RA. There are very few studies in India about lipid profile abnormality in rheumatoid arthritis and its relationship with the severity of the disease in RA patients. There is lacuna of knowledge about this aspect of disease in Indian patients. This study aims to address this issue.

AIM

To study lipid profile abnormalities and its relationship with the severity and number of ACR criteria of Rheumatoid Arthritis.

MATERIALS AND METHODS

This cross-sectional study was conducted from August 2009 – August 2011, patients fulfilling the American College of Rheumatology 1987 criteria for Rheumatoid Arthritis,³ newly diagnosed and patients on treatment for Rheumatoid Arthritis are taken into consideration. Dyslipidaemia defined using the high cut-off values of National Cholesterol Education Programme-Adult Treatment Panel. Disease Activity Score DAS-28(4) was employed to calculate the disease activity. For all patients after an overnight fasting blood samples were collected and serum was separated and Fasting Lipid Profile was done enzymatically using standardised Flex® reagent cartridges for Total Cholesterol, High Density Lipoproteins, Low Density Lipoproteins and Triglycerides. RA factor was done using Latex Agglutination Test. ESR for assessing DAS 28 was done using Wintrobe's method. The significance of difference in mean between two groups were analysed by student t-test. The correlation between Lipid profile and Disease Activity, number of ACR criteria fulfilled and newly diagnosed and old cases was calculated by using the Pearson's correlation coefficient method.

Statistical significance was taken when p value < 0.05. Statistical analysis was carried out using standard formulae. Microsoft Excel 2007 and SPSS (statistical package for social sciences) version 13 software was used for data entry and analysis.

RESULTS

A total of 80 patients with Rheumatoid Arthritis (newly diagnosed and known cases) were studied. In this study, 67 (83.8%) were females and 13 (16.3%) were males, the female to male ratio is 5.15. All the 80 patients fulfilled the American College of Rheumatology 1987 criteria for the diagnosis of Rheumatoid Arthritis 25. The age of patients ranged from 24 to 80 yrs., with mean age of 44.2 ± 11.3 yrs. Out of 80 patients, 35 (43.75%) fulfilled 4 ACR criteria, 34 (42.5%) fulfilled 5 ACR criteria and 11 (13.75%) fulfilled 6&7 criteria. Out of 80 patients, 44 (55%) had Dyslipidaemia, of which 41 (51.25) had low High Density Lipoproteins. In this study, TC decreases with the increase in the activity of the disease with a P-value of 0.063. LDL decreases with the increase in the activity of the disease with a P-value of 0.091. HDL decreases with the increase in the activity of the disease with a P-value of <0.001. Triglycerides decreases with the increase in the activity of the disease with a P-value of 0.005. TC/HDL increases with the increase in the activity of the disease with a P-value of 0.0001. In this study, TC decreases with the increase in the number of ACR criteria fulfilled with a P-value of 0.024. LDL was low in patients fulfilling 6&7 ACR criteria fulfilled with a P-value of 0.056. HDL decreases with the increase in the number of ACR criteria fulfilled with a P-value of 0.014. TG decreases with the increase in the number of ACR criteria fulfilled with a P-value of 0.028. TC/HDL increases with the increase in the number of ACR criteria fulfilled with a P-value of 0.234.

CONCLUSION

Lipid Profile in Rheumatoid Arthritis patients depends on the severity of the disease. There is an inverse relationship between TC, LDL-C, HDL-C and Triglycerides and severity of the Rheumatoid arthritis. Which is statistically significant for HDL-C and Triglycerides. There is direct relationship between TC/HDL-C and severity of disease which is statistically significant. These factors in part explain the high risk of Coronary Artery Disease in patients with Rheumatoid Arthritis and the importance of effective treatment of RA.

KEYWORDS

Lipid Profile, Rheumatoid Arthritis, Disease Severity.

INTRODUCTION: Rheumatoid arthritis is a well-known chronic inflammatory disease which affects multiple joints usually in a symmetrical manner. Autoimmunity is the mechanism proposed for the inflammation of the joints and other manifestations of rheumatoid arthritis.

Inflammation of the joints can lead to joint destruction and formation of deformities if the disease is not controlled well.

Apart from the joints RA can affect numerous other systems of the body like cardiovascular, neurological, haematological, skin blood vessels, etc.

Life expectancy in rheumatoid arthritis patients seems to be reduced compared to their normal counter parts ranging from 0.87 to 3.0. times.⁴

The most common cause of death of RA patients has been found to be cardiovascular disease. The often proposed reason being the chronic elevation of inflammatory markers leading to accelerated atherosclerosis.^{5,4,6} An earlier study had showed that the incidence of coronary artery disease was about 50% higher in young females with rheumatoid arthritis.⁷

Apart from the usual risk factors like diabetes, hypertension, obesity smoking, physical inactivity, two things have been commonly implicated as the explanation for accelerated atherosclerosis in RA. Apart from the usual risk factors like diabetes, hypertension, obesity smoking, physical inactivity.

One being chronic inflammatory state and the other being dyslipidaemia.^{1,2}

Most studies have shown that the lipid profile of patients with active or untreated RA is primarily characterised by a decrease in the serum levels of HDL-C. The significant reduction in HDL increases in the TC/HDL-C ratio.⁸ which represents the atherogenic index and this could explain the increased CAD risk in these patients. The risk of myocardial infarction increases considerably when this ratio is higher than five, and it should ideally be four or less.^{8,9} Reductions in HDL and TC also correlated with the disease activity, suggesting a potential role for inflammation in the atherogenic profile and the higher atherosclerotic risk observed in RA.¹⁰

However, contrasting results have been published on the serum levels of TC and LDL-C.^{8,9,10,11,12,13} in RA.

The discrepancies in the lipid values observed in the various studies might be due to differences in studied populations as well as in disease activity. There are few studies in India about lipid profile abnormality in rheumatoid

arthritis and its relationship with the severity of the disease in RA patients. There is lacuna of knowledge about this aspect of disease in Indian patients. This study aims to address this issue.

AIMS OF THE STUDY:

1. To study lipid profile abnormalities and its relationship with the severity of Rheumatoid Arthritis.
2. To study the relationship between the number of ACR criteria fulfilled and Lipid Profile abnormalities.
3. To study the lipid profile abnormalities in newly diagnosed and known cases of rheumatoid arthritis.

MATERIALS AND METHODS:

1. **Source of Data:** Eighty patients attending medicine and rheumatology outpatient department and patients admitted in the General Medicine Department at Sri Ramachandra Medical College.
2. **Duration of Study:** This study was conducted from August 2009 – August 2011.
3. **Study Design:** A cross-sectional study design was chosen.
4. **Inclusion Criteria:** Patients fulfilling the American College of Rheumatology 1987 criteria for Rheumatoid Arthritis.³ Newly diagnosed and patients on treatment for Rheumatoid Arthritis are taken into consideration.
5. **Exclusion Criteria:** Patients having comorbid conditions known to influence lipids like
 - Malabsorption syndrome.
 - Nephrotic syndrome.
 - Chronic Kidney Disease.
 - Diabetes mellitus.
 - Thyroid disorders.
 - Liver disorders.
 - Coronary Artery Disease.
 - Intake drugs like.
 - Lipid modifying drugs.
 - Oral contraceptives.
6. **Methods of Study:** The study population includes 80 patients with Rheumatoid arthritis. Dyslipidaemia defined using the high cut-off values of National Cholesterol Education Programme- Adult Treatment Panel. Disease Activity Score DAS-28(4) was employed to calculate the disease activity.

Laboratory Measurements: For all patients after an overnight fasting, blood samples were collected and serum was separated and Fasting Lipid Profile was done enzymatically using standardised Flex® reagent cartridges for Total Cholesterol, High Density Lipoproteins, Low Density Lipoproteins and Triglycerides.

RA factor was done using Latex Agglutination Test.

ESR for assessing DAS 28 was done using Wintrobe’s method.

Financial Support – Nil.

STATISTICAL ANALYSIS: Statistical analysis was carried out for 80 RA patients, after categorising each variable. Base line data was collected from patients - Age, sex, BMI, Fasting Lipid profile, ESR, Visual Analogue Scale (VAS) were analysed using DAS 28(4).^{14,15}

Disease activity calculated using DAS 28(4)^{14,15}
 $DAS28 = 0.56 \times \sqrt{TJC28} + 0.28 \times \sqrt{SJC28} + 0.70 \times \ln(ESR) + 0.114 \times VAS.$

Tender Joint Count (TJC) and Swollen Joint Count (SJC) is measured by looking for tenderness and swelling of the 10 Metacarpophalangeal joints and 10 proximal Interphalangeal joints of upper limbs and wrists-2, elbows-2, shoulders-2, knees-2, VAS (visual analogue scale) or SA is the subjective assessment of symptoms over the past 7 days as described by the patient, DAS 28 is calculated using the above formula using DAS calculator.

≤ 3.2	Low Disease Activity
3.2 to ≤ 5.1	Moderate Disease Activity
> 5.1	High Disease Activity
Activity of the Disease based on DAS 28.^{14,15}	

The significance of difference in mean between two groups were analysed by student t-test. The correlation between Lipid profile and Disease Activity, number of ACR criteria fulfilled and newly diagnosed and old cases was calculated by using the Pearson's correlation coefficient method.

Statistical significance was taken when p value < 0.05. Statistical analysis was carried out using standard formulae. Microsoft Excel 2007 and SPSS (statistical package for social sciences) version 13 software was used for data entry and analysis.

RESULTS:

Variable	Values
Age	44.2±11.307
Sex- M/F	67/13
BMI	22.747±2.562
Duration of Disease (Yrs.)	2.519±3.241

RESULTS:

- A total of 80 patients with Rheumatoid Arthritis (newly diagnosed and known cases) were studied.
- The patients were studied on the basis of the severity of the disease based on DAS 28, Duration of disease, Number of ACR 1987 criteria fulfilled with reference to the Lipid profile of the patient.
- In this study, 67 (83.8%) were females and 13 (16.3%) were males, the female to male ratio is 5.15.
- All the 80 patients have fulfilled the American College of Rheumatology 1987 criteria for the diagnosis of Rheumatoid Arthritis 25.
- The age of patients ranged from 24 to 80 yrs., with mean age of 44.2±11.3 yrs.
- Based on severity of disease, 31 (38.8%) of patients had Low Disease Activity, 22 (27.5%) patients had Moderate Disease Activity and 27 (33.8%) had Severe Disease Activity.
- 12.5% of patients had BMI <20, 71.3% of patients had BMI 20 to 25, 16.3% of patients had BMI 25 to 30, the mean BMI 22.747±2.562.
- Out of 80 patients, 20% are newly diagnosed and 80% were known cases of Rheumatoid Arthritis who are on and off treatment.
- Out of 80 patients, 35 (43.75%) fulfilled 4 ACR criteria, 34 (42.5%) fulfilled 5 ACR criteria and 11 (13.75%) fulfilled 6&7 criteria.
- Out of 80 patients, 44(55%) had Dyslipidaemia, of which 41(51.25) have low High Density Lipoproteins.

Relationship of Lipid Profile with Disease Activity:

- **Total Cholesterol (TC):** The mean TC in patients with Low Disease Activity is 167.9355± 15.5046 mg/dL, in patients with Moderate Disease Activity is 162.8636± 15.9412 mg/dL, in patients with Severe Disease Activity is 157.7407± 17.1522 mg/dL. In this study, TC decreases with the increase in the activity of the disease with a P-value of 0.063.

Among 80 patients, 1 patient had TC>200 mg/dL who has Low Disease Activity.

- **Low Density Lipoproteins (LDL):** The mean LDL in patient with Low Disease Activity is 102.8387± 13.2793 mg/dL, in patients with Moderate Disease Activity is 100.9545±14.9999 mg/dL, in patients with Severe Disease Activity is 93.4815± 20.7037 mg/dL. In this study, LDL decreases with the increase in the activity of the disease with a P-value of 0.091.
- **High Density Lipoproteins (HDL):** The mean HDL in patient with Low Disease Activity is 44.1935± 6.9061 mg/dL, in patients with Moderate Disease Activity is 39.4091± 6.1074 mg/dL, in patients with Severe Disease Activity is 33.037± 6.4359 mg/dL. In this study, HDL decreases with the increase in the activity of the disease with a P-value of <0.001.

Among patients with severe disease activity, 18 (85.18%) had low HDL levels, 13 (59.09%) with moderate activity and 5 (16.13%) with low disease activity had low HDL levels.

- **Triglycerides (TG):** The mean TG in patient with Low Disease Activity is 128.871±14.957 mg/dL, in patients with Moderate Disease Activity is 125.2727±17.7205 mg/dL, in patients with Severe

Disease Activity is 114 ± 18.7103 mg/dL. In this study, Triglycerides decreases with the increase in the activity of the disease with a P-value of 0.005.

- **TC/HDL:** The mean TC/HDL in patient with Low Disease Activity is 3.882 ± 0.654 , in patients with Moderate Disease Activity is 4.199 ± 0.582 , in patients with Severe Disease Activity is 4.898 ± 0.967 . In this study, TC/HDL increases with the increase in the activity of the disease with a P-value of 0.0001.

Relationship of Lipid Profile with Number of ACR Criteria:

- **Total Cholesterol:** The mean TC in patients who fulfilled 4 ACR criteria is 166.057 ± 16.766 mg/dL, in patients fulfilling 5 criteria is 164.029 ± 16.325 mg/dL, in patients fulfilling 6&7 criteria is 150.818 ± 11.626 mg/dL. In this study TC decreases with the increase in the number of ACR criteria fulfilled with a P-value of 0.024.
- **Low Density Lipoproteins (LDL):** The mean LDL in patients who fulfilled 4 ACR criteria is 100.229 ± 15.322 mg/dL, in patients fulfilling 5 criteria is 101.676 ± 18.140 mg/dL, in patients with fulfilling 6&7 criteria is 88 ± 14.331 mg/dL. In this study LDL was low in patients fulfilling 6&7 ACR criteria fulfilled with a P-value of 0.056.
- **High Density Lipoproteins (HDL):** The mean HDL in patients who fulfilled 4 ACR criteria is 40.971 ± 7.382 mg/dL, in patients fulfilling 5 criteria is 39.176 ± 8.451 mg/dL, in patients with fulfilling 6&7 criteria is 33 ± 5.899 mg/dL. In this study HDL decreases with the increase in the number of ACR criteria fulfilled with a P-value of 0.014.
- **Triglycerides (TG):** The mean TG in patients who fulfilled 4 ACR criteria is 126.571 ± 18.724 mg/dL, in patients fulfilling 5 criteria is 123.176 ± 16.123 mg/dL, in patients with fulfilling 6&7 criteria is 110.09 ± 17.323 mg/dL. In this study TG decreases with the increase in the number of ACR criteria fulfilled with a P-value of 0.028.
- **TC/HDL:** The mean TC/HDL in patients who fulfilled 4 ACR criteria is 4.164 ± 0.772 , in patients fulfilling 5 criteria is 4.349 ± 0.994 , in patients with fulfilling 6&7 criteria is 4.667 ± 0.671 . In this study TC/HDL increases with the increase in the number of ACR criteria fulfilled with a P-value of 0.234.

Relationship of Lipid Profile with New and Known Cases of Rheumatoid Arthritis:

- Patients who were newly diagnosed to have RA have a mean TC of 159.125 ± 19.151 mg/dL and already diagnosed patients have a TC of 164.093 ± 15.877 mg/dL with a P-value of 0.286.
- Patients who were newly diagnosed to have RA have a mean LDL of 95.75 ± 24.453 mg/dL and already diagnosed patients have a TC of 100.016 ± 14.54 mg/dL with a P-value of 0.369.
- Patients who were newly diagnosed to have RA have a mean HDL of 33.1875 ± 7.952 mg/dL and already diagnosed patients have a TC of 40.594 ± 7.389 mg/dL with a P-value of 0.001.

- Patients who were newly diagnosed to have RA have a mean Triglycerides of 115 ± 21.596 mg/dL and already diagnosed patients have a TC of 124.828 ± 16.687 mg/dL with a P-value of 0.051.
- Patients who were newly diagnosed to have RA have a mean TC/HDL of 4.999 ± 1.129 and already diagnosed patients have a TC of 4.14 ± 0.701 mg/dL with a P-value of 0.051.

Disease activity and lipid profile with BMI:

- Patient with BMI < 20 had more Disease Activity 5.408 ± 1.943 compared to patients with BMI 20 – 25 and 25 – 30 with DAS of 4.156 ± 1.522 and 4.147 ± 1.165 respectively, with a P-value of 0.059.
- Patients with BMI <20 had low TC, LDL, HDL, Triglycerides, compared to patients with BMI between 20 to 25 who had low values as compared to patients with BMI between 25 to 30, and TC/HDL is not related to the BMI. The P-values are significant for TC, LDL, Triglycerides and insignificant for HDL and TC/HDL.

The unfavourable lipid profile in our study can explain the increased cardiovascular mortality in RA patients. The explanation given by western studies for increased cardiovascular mortality in RA patients as follows.

1. The presence of circulating anti-oxidised VLDL and LDL antibodies in RA, may be responsible for the reduced level of total cholesterol and LDL cholesterol.¹⁵
2. Cardiovascular disease in RA may result from accelerated atherosclerosis caused by clinical or subclinical vasculitis.⁹
3. Reduced cardiovascular fitness caused by immobility.¹⁶
4. The inflammatory environment and disturbed antioxidant mechanisms in RA may promote LDL oxidation, thereby facilitating atherogenesis at lower ambient lipid concentrations and placing RA patients at higher cardiovascular risk.⁹
5. Lipoprotein (a), an important independent factor in atherogenesis and thrombogenesis is increased in RA correlating positively with the acute phase response.¹⁷
6. Increased homocysteine level,¹⁸ and increased thrombotic factors.¹⁹
7. Inflammatory mechanisms responsible for synovial lesions in patients with RA may directly participate in producing atherosclerotic lesions resulting in excess cardiovascular disease in RA patients.²⁰

ABBREVIATIONS:

TC - Total Cholesterol.
 LDL-C - Low Density Lipoprotein cholesterol.
 HDL-C - High Density Lipoprotein Cholesterol.
 TG – Triglycerides.
 ACR - American College of Rheumatology.
 DAS 28 - Disease Activity Score of 28 joints.
 ESR - Erythrocyte Sedimentation Rate.
 TJC - Tender Joint Count.
 SJC - Swollen Joint Count.
 VAS - Visual Analogue Scale.

NCEP - National Cholesterol Education Programme.
 ATP III - Adult Treatment Panel III.
 ND - Newly Diagnosed.

CONCLUSION:

- Lipid Profile in Rheumatoid Arthritis patients depends on the severity of the disease.
- There is an inverse relationship between TC, LDL-C, HDL-C and Triglycerides and severity of the Rheumatoid Arthritis which is statistically significant for HDL-C and Triglycerides. There is direct relationship between TC/HDL-C and severity of disease which is statistically significant. These factors in part explain the high risk of Coronary Artery Disease in patients with Rheumatoid Arthritis and the importance of effective treatment of RA.
- There is an inverse relationship between TC, HDL-C, LDL-C and Triglycerides and the number of ACR criteria fulfilled which is statistically significant for TC, HDL-C and Triglycerides, and direct relationship between TC/HDL-C and severity of disease which is not statistically significant.
- Newly diagnosed patients have low levels of TC, HDL-C, LDL-C and Triglycerides statistically significant for HDL-C owing to the severity of the disease in patients not on treatment and the possible benefit of treatment.
- Early treatment of Rheumatoid Arthritis aimed at remission or reducing the severity of the disease has a favourable effect on the Lipid Profile of the patients with Rheumatoid Arthritis which is one of the important factors for Coronary Artery Disease which is the commonest cause of death in patients with RA.^{2,3,5}
