ABSTRACT

BACKGROUND
Neodymium-doped Yttrium Aluminium Garnet (Nd:YAG) laser is a solid state laser in which Nd:YAG is used as a laser medium. Nd:YAG laser posterior capsulotomy introduced a technique for closed eye, effective and relatively safe opening of the opacified posterior capsule and laser capsulotomy rapidly became the standard of care.

The aim of the study is to study the visual outcome following Nd:YAG laser capsulotomy for posterior capsular opacification.

MATERIALS AND METHODS
This is a prospective study of 100 patients conducted in the Department of Ophthalmology, Government General Hospital, Kakinada, over a period of 2 years.

RESULTS
The observations from the study were analysed and compared with the existing studies in the literature.

CONCLUSION
Nd:YAG laser capsulotomy is safest and excellent procedure for restoring vision provided the vision loss is only due to posterior capsular opacification.

KEYWORDS
Capsular Opacification, Capsulotomy, YAG Laser, Intraocular Pressure.

HOW TO CITE THIS ARTICLE: Pinipe SD, Varanasi SS. A clinical study of visual outcome and IOP changes following YAG-capsulotomy in postoperative cataract patients. J. Evid. Based Med. Healthc. 2017; 4(94), 5858-5861. DOI: 10.18410/jebmh/2017/1179

BACKGROUND
Nd:YAG capsulotomy is a special laser treatment used to improve the vision after cataract surgery followed by posterior capsule opacification. PCO is a common long-term complication of cataract surgery occurs about 2 years after surgery in 50% of the patients that causes decreased vision, glare and other symptoms similar to that of the original cataract. Posterior Capsular Opacification (PCO) remains one of the most common postoperative morbidities in modern day cataract surgery and Nd:YAG posterior capsulotomy is one of the most commonly performed surgical procedures.1

Posterior capsule opacification is the most common delayed complication of cataract surgery. The incidence of PCO was reported to be 20.7% at 2 years and 28.5% at 5 years after cataract surgery.2

PCO is an extremely common development in patients after cataract extraction, and in many cases, it may not be immediately obvious, whether it is visually significant. Patients may have reduced vision from other undetermined causes or have some measures of visual function that are not reduced at all.3 YAG laser capsulotomy is the only way to treat this. Apart from affecting the vision, the thickening does not damage the eye in anyway. The patient complains of decreased visual acuity, glare and sensitivity to light. The YAG laser posterior capsulotomy has become standard treatment for this anomaly- an opening is created in the opacified posterior capsule, which immediately improves visual acuity.4

Since the use of Nd:YAG laser for posterior capsulotomy, the procedure has been gradually replacing the surgical capsulotomy as it is less invasive and can be performed as an outpatient procedure. Nd:YAG laser capsulotomy showed itself to be an effective alternative to surgical discission avoiding such complications as endophthalmitis and vitreous loss.5

Hence, in the present study, effort is made to study the visual outcome, IOP changes and complications following Nd:YAG laser capsulotomy.

Aims and Objectives of the Study
1. The aim is to study the visual outcome and analyse the clinical results of Nd:YAG laser posterior capsulotomy in terms of efficacy, safety and complications in 100 eyes with posterior capsule opacification after small incision
A study was conducted to investigate the incidence of posterior capsule opacification (PCO) following cataract surgery, taking into account factors such as age, sex, and the duration between cataract extraction and the development of PCO.

**Materials and Methods**

The study was a hospital-based, prospective observational study conducted in the Department of Ophthalmology at Kakinada Hospital, covering the period from December 2014 to August 2016. A total of 100 eyes from 100 patients were included in the study. Exclusion criteria included patients under 5 years of age, those with subluxated intraocular lenses, and those who were uncooperative or had mental retardation or neurological problems. Patients with postoperative complications like endophthalmitis or retinal detachment were also excluded.

**Observation and Results**

**Inclusion Criteria**
1. Evidence of posterior capsular thickening or opacification on examination with slit-lamp.
2. Postoperative cataract surgery, decrease in vision by at least 3 lines on Snellen's chart.
3. At least 3 months interval between cataract surgery and development of posterior capsular opacification.

**Exclusion Criteria**
1. Patients <5 years of age.
2. Eyes with subluxated intraocular lens.
3. Cases with postoperative complications like endophthalmitis.
4. Uncooperative patients, e.g., patient with mental retardation, neurological problems.
5. Posterior capsular opacification in aphakic eyes.

**Post Laser Follow-Up**

Intraocular pressure was recorded every 1 hour, 4 hours, 1 day, 1 week, 1 month, 3 months, and 6 months after capsulotomy, and the patient was sent home to come for follow-up after 1 week, 1 month, 3 months, and 6 months. The patient receives the following treatment:

- Topical timolol maleate 0.5% b.i.d. for 1 week.
- Topical antibiotic and steroid eye drops 1 q.i.d. for 1 week.
- Oral acetazolamide tablets 250 mg q.i.d. for 5 days only when IOP is not controlled with above medication.

**Observation and Results**

**Age Distribution**

An attempt was made to see the age of the patient at the time of cataract extraction and development of PCO. The main aim was to look for the age group in which posterior capsule opacification occurs earlier. It has been shown that in patients under 40 years of age, the posterior capsule opacification was early, i.e., before 1 year. So, it can be stated that younger the age, earlier will be the posterior capsule opacification.

**Duration between Cataract Extraction and Development of PCO**

From this, it can be found that posterior capsule opacification occurs within 3 years in about 68% of cases within the first year.

**Grading of Posterior Capsular Opacity**

Posterior capsule opacification has been graded as mild, moderate, and severe depending on slit-lamp examination and upon the visibility of fundus by direct and indirect ophthalmoscopy as follows.

**Total 100 eyes**

**Sex Distribution**

Out of 100 patients in the study group, 52 are males and 48 are females. It was observed that the incidence of posterior capsule opacification is more in males.
Complications of YAG Capsulotomy. Cases were examined within 4 hours and 24 hours for complications of Nd:YAG capsulotomy. Total number of eyes examined were 100 and results were analysed and it was observed that raised intraocular pressure is the commonest complication followed by YAG capsulotomy.

Table 4. Showing Complications of YAG Capsulotomy

Late Postoperative Complications. In the follow up period of 1 week, 4 weeks, 12 weeks and 24 weeks, cases were examined for complications like cystoid macular oedema, retinal detachment and chronic glaucoma. None of the cases presented with cystoid macular oedema, retinal detachment and chronic open-angle glaucoma.

DISCUSSION
Posterior capsule opacity is a major complication of cataract surgery with or without intraocular lens implantation. The use of Nd:YAG laser has definitely simplified the treatment of posterior capsule opacification. Another great advantage is that is entirely non-invasive. The non-invasive technique of Nd:YAG laser has become popular for doing posterior capsulotomy and it has been established as a standard treatment for PCO replacing surgical capsulotomy. In our short study of 100 cases, the main aim was to evaluate the results of Nd:YAG laser capsulotomy in 100 eyes of 100 patients. All the 100 patients had visual acuity improvement of 1 or more lines after capsulotomy. No one had further decline in visual acuity after capsulotomy.

The average age of presentation of PCO is similar in all the studies. It has been shown that in patients under 40 years of age, the PCO was early, i.e. before 1 year and it is 2 years within the patients of age group 42-60 years.

The average time interval of cataract surgery and Nd:YAG laser capsulotomy was 23 months.

PCO occurred in young patients (under 40) twice as often as in the other groups of age. Technique of cataract extraction had an influence on the incidence of PCO as well.7
So, it can be stated that younger the age, earlier will be the PCO.

In the present study, though there is transient rise in IOP at the end of 4 hours, there is no much change in IOP at the end of 1 week.

In our study, we highlighted increase in the IOP was significantly related to the IOP measurement 1 hour after the capsulotomy, whereas difference between baseline and final IOP at 1 week was not significant.

Raised intraocular pressure (IOP > or = 5 mmHg from the baseline) after Nd:YAG laser posterior capsulotomy was noted in both the 'low energy' and the 'high energy' groups, but it was more common in the 'high energy' group (p<0.001, r=0.512).  

In the present study, rise in IOP is the most common complication followed by iritis, vitritis, pitting of IOL and lastly hyphema, which was also the same complication seen in other studies.

The rise in IOP is only transient. There is no permanent rise in IOP except in known glaucoma cases. This rise in IOP can be prevented by giving pre-laser antiglaucoma medication and prescribing antiglaucoma medications like 0.5% timolol eye drops and Tab. Diamox 250 mg BD after capsulotomy.

Postoperative visual improvement was 6/24 to 6/6. All patients showed post laser IOP rise that was controlled by topical beta-blockers and steroids effectively.

CONCLUSION
Improvement in visual acuity with Nd:YAG laser capsulotomy is excellent. Complications with Nd:YAG laser capsulotomy are minimal and transient.

Careful follow-up with Nd:YAG laser capsulotomy is important and topical timolol maleate 0.5% drops after capsulotomy prevents spikes of IOP, which may occur in some cases. Oral acetazolamide along with topical timolol can be used in patients who show rise of IOP uncontrollable with topical timolol alone.

Proper selection of case is important. Pitting of IOL may occur in uncooperative patients. Nd:YAG laser capsulotomy should be done with caution in patients with increase in axial length, peripheral degenerations and retinal detachment in other eyes as these patients are at increased risk of retinal detachment.

Nd:YAG laser capsulotomy is a safe method of restoring vision in patients with posterior capsule opacification. The results Nd:YAG laser capsulotomy were comparable to those reported in literature.

Complications like transient rise of intraocular pressure, vitritis, bleeding from iris, pitting of intraocular lens and iritis have been reported in our study. Visual acuity improved to 6/6 in 16 cases, 6/9 in 36 cases, 6/12 in 16 cases, 6/18 in 10 cases, 6/24 in 8 cases, 6/36 in 7 cases, 6/60 in 4 cases and 3 cases were lost for follow-up.

To conclude, Nd:YAG capsulotomy is a safe procedure. Since significant pressure spikes occur after laser procedure, it is important to put the patients on topical timolol maleate 0.5% drops. Intraocular pressure after 1 hour, 4 hours and 1 week is important. When the patient comes for follow-up after 1 week, 4 weeks and 24 weeks, it is important to look for cystoid macular oedema and retinal detachment and endophthalmitis.
