### ABSTRACT

#### BACKGROUND

Acute appendicitis is one of the most common surgical emergencies with a lifetime presentation of approximately 1 in 7. Its incidence is 1.5-1.9/1000 in males and females. Surgery for acute appendicitis is based on history, clinical examination and laboratory investigations (e.g. WBC count). Imaging techniques add very little to the efficacy in the diagnosis of appendix. A negative appendectomy rate of 20-40% has been reported in literature. A difficulty in diagnosis is experienced in very young patients and females of reproductive age. The diagnostic accuracy in assessing acute appendicitis has not improved in spite of rapid advances in management.

#### MATERIALS AND METHODS

The modified Alvarado score was applied and assessed for its accuracy in preparation diagnosis of acute appendicitis in 50 patients. The aim of our study is to understand the various presentations of acute appendicitis including the age and gender incidence and the application of the modified Alvarado scoring system in our hospital setup and assessment of the efficacy of the score.

#### RESULTS

Our study shows that most involved age group is 3<sup>rd</sup> decade with male preponderance. On application of Alvarado score, nausea and vomiting present in 50% and anorexia in 30%, leucocytosis was found in 75% of cases. Sensitivity and specificity of our study were 65% and 40% respectively with positive predictive value of 85% and negative predictive value of 15%.

#### CONCLUSION

This study showed that clinical scoring like the Alvarado score can be a cheap and quick tool to apply in emergency departments to rule out acute appendicitis. The implementation of modified Alvarado score is simple and cost effective.

#### KEYWORDS

Acute Appendicitis, Alvarado Score, Scoring System, Negative Appendectomy.

**HOW TO CITE THIS ARTICLE:** Sujatha V, Uma D. Modified Alvarado scoring in acute appendicitis. J. Evid. Based Med. Healthc. 2016; 3(98), 5369-5373. DOI: 10.18410/jebmh/2016/1116

#### BACKGROUND

One of the commonest clinical presentation that requires emergency surgery is acute appendicitis.<sup>1,2</sup> It is rare in infancy and among the elderly, but is common in children, teenagers and young adults.<sup>3</sup> Patients history and physical examination is very important for proper diagnosis.<sup>4</sup> Diagnosis of appendicitis has an considerable rate of negative appendectomy varying from 20-40% and associated morbidity of around 10%.<sup>5</sup> The classical signs and symptoms of acute appendicitis were first reported by Fitz in 1886. Since then, it has remained the most common diagnosis for hospital admission requiring laparotomy.<sup>1,2</sup> The diagnosis of appendicitis can be difficult occasionally taxing the diagnostic skills of even most experienced surgeon. Attempts to increase the diagnostic accuracy of acute

appendicitis has included computer-aided diagnosis, imaging by USG, laparoscopy and even radioactive isotope imaging.<sup>6,7,8,9</sup> Various scoring systems has been devised to aid diagnosis. The Alvarado score was described in 1886.<sup>10</sup> Our study is based on application of modified Alvarado score in evaluation of acute appendicitis.

#### AIM OF STUDY

1. To understand the various presentations of acute appendicitis including the age and gender incidence.
2. The application of the modified Alvarado scoring system in our hospital setup and assessment of the efficacy of the score.
3. To recognise the sensitivity and specificity of the scoring system.
4. To compare our evaluation with the available national and international standards.
5. The scoring was designed to decrease the negative appendectomy rate thereby reducing the mortality.

**MATERIALS AND METHODS**

A total of 50 patients who were admitted on emergency basis were analysed for this prospective study conducted from 2014 to 2016 at K.A.P.V. Medical College Hospital, Tiruchirappalli.

**Inclusion Criteria**

Patients with provisional clinical diagnosis of acute appendicitis.

**Exclusion Criteria**

1. Paediatric age group.
2. Pregnancy.
3. Elderly above 70 years of age.

**ALVARADO SCORING SYSTEM**

The scoring system was introduced as an adjunct to the diagnosis in order to correct the previous high false positive rate based on three symptoms, three signs and two laboratory findings.<sup>10</sup> All the patients included in the study whose specimen were sent for HPE was recorded. The patients were reviewed up in the Alvarado Score. Each of the preoperative signs and symptoms and postoperative lab findings were awarded points in the Alvarado scoring system.

| Symptoms                           | Scores    |
|------------------------------------|-----------|
| Migratory RIF pain                 | 1         |
| Anorexia                           | 1         |
| Nausea/vomiting                    | 1         |
| Signs                              |           |
| Tenderness RIF                     | 2         |
| Rebound tenderness RIF             | 1         |
| Increase in body temperature       | 1         |
| Lab Finding                        |           |
| Leucocytosis                       | 2         |
| Shift to left neutrophils          | 1         |
| <b>Total</b>                       | <b>10</b> |
| <b>Alvarado Score<sup>10</sup></b> |           |

| Score            | Inference                                                                            |
|------------------|--------------------------------------------------------------------------------------|
| 1-4              | Not likely to have appendicitis                                                      |
| 5-6              | To have findings compatible with appendicitis, but not convincing to warrant surgery |
| 7-8              | To have probable acute appendicitis                                                  |
| 8-10             | Almost definite diagnosis of acute appendicitis                                      |
| <b>Inference</b> |                                                                                      |

The Alvarado score may increase or decrease on reassessment of patients, which were considered under review category (score 5-6).

We used a slightly modified version of Alvarado score by excluding one laboratory finding 'shift to left of Neutrophil Maturation' (Score 1). This was done because of non-

availability of this test in emergency situations. Hence, patients calculated out of 9 than 10 score.

- 6-9 - Subjected for appendectomy.
- <6 - Were not considered and were taken in review category for observation.

After subjecting the patients in review category to 24 hrs., observation regardless of score surgery was performed on patients who were thought on clinical grounds to require surgery.

**RESULTS**

Out of 60 cases, 50 cases were taken up for surgery. The remaining 10 cases with low scores and not convincing to warrant emergency surgery were excluded.

| Age (Yrs.)              | Number of Patients | Percentage |
|-------------------------|--------------------|------------|
| 0-10                    | -                  |            |
| 11-20                   | 12                 | 24         |
| 21-30                   | 18                 | 36         |
| 31-40                   | 12                 | 24         |
| 41-50                   | 5                  | 10         |
| 51-60                   | 1                  | 2          |
| 61-70                   | 2                  | 4          |
| <b>Age Distribution</b> |                    |            |

In our analysis, it has been observed that the most involved age group is third decade of life followed by second decade of life.

| Sex                     | Cases | Percentage |
|-------------------------|-------|------------|
| Male                    | 35    | 70         |
| Female                  | 15    | 30         |
| <b>Sex Distribution</b> |       |            |

In this study, number of male patients (35) were more than the number of female patients.

|                             | Number of Patients | Percentage |
|-----------------------------|--------------------|------------|

| <b>Sensitivity and Specificity</b> |             |             |

Initial assessment can be improved by clinical scoring systems such as the Alvarado scoring system based on history, physical examination and laboratory investigations.<sup>13,14</sup> On a comparative basis, the sensitivity is high in males, but have a low specificity in females. The above findings depict that modified Alvarado scoring system is efficacious in males, thereby decreasing the morbidity. Traditionally surgeons may have a more liberal attitude towards laparotomy in young female patients because of the increased risk of infertility following perforated appendix, but the application of modified Alvarado score may be useful in important diagnostic accuracy. Ultrasonogram is considered resource consuming and therefore not useful as a general

diagnostic tool in all patients. Laparoscopy has recently gained more attention as having both diagnostic property and therapeutic possibility, which is promising, however, it is an invasive procedure performed under general anaesthesia and with regard to feasibility and cost utility, its place still remains to be shown with patients in suspected appendicitis. Recently, various examination tools including USG and CT diagnosis have been employed to improve diagnostic accuracy. Results of our study are comparable with literature. Negative appendectomy rate in our study was 16%. Removal of some normal appendices is found to lower the rate of perforation and consequently mortality. Literature shows that negative appendectomy rate is less than 10-15%, 16% in Talukder et al 2009, 12% in Rajashekar Jade et al 2016. Our study shows that the application of Alvarado scoring system in diagnosis of acute appendicitis can provide a high degree of patient's predictive value and thus diagnostic accuracy. Our study also revealed that Alvarado scoring system is more helpful in male patients by showing lower negative appendectomy rate and high positive predictive value for male patients as compared to females. In females, additional investigations maybe required to confirm diagnosis. Literature also supports this observations.<sup>16,17</sup>

**STATISTICAL ANALYSIS**

To statistically determine the efficacy of modified Alvarado score system, we used statistical software SPSS and the 't' test to find out the above-mentioned system was significant. The mean and standard deviation were calculated. The mean values were compared using 't' test. Cross tabulation was also done, sensitivity and specificity estimated.

**Case Processing Summary**

**Score 1 \* Diag Cross Tabulation**

| Alvarado Score               | HPE Positive | HPE Negative |
|------------------------------|--------------|--------------|
| >7                           | 35           | 6            |
| <7                           | 5            | 4            |
| <b>Total Number of Cases</b> | <b>40</b>    | <b>10</b>    |

The mean Alvarado score for HPE positive is 7.87 with a standard deviation 0.96, whereas for negative HPE the score is 7 (0.94).

't' value is 2.574, which is statistically significant.

'p' value is 0.013.

We have also compared Alvarado score of >7 with HPE outcome of 40 HPE positive patients. 35 patients were having >7 Alvarado score showed that the sensitivity is 87.5%. Those who had negative HPE report having a score of <7 showed that the specificity is 40%. The false positive is 6% and false negative is 5% for both male and females.

The study has a positive predictive value of 85%.

### CONCLUSION

Acute appendicitis is one of the most frequent reasons for emergency abdominal operations. Correct preoperative diagnosis sometimes can be difficult. In our country, the surgeon should largely rely upon clinical findings. This study showed that clinical scoring like the Alvarado score can be a cheap and quick tool to apply in emergency departments to rule in acute appendicitis. This scoring system is a dynamic one allowing observation and clinical re-evaluation of the clinical picture. Its application improves diagnostic accuracy and consequently reduces negative exploration and complication rates (e.g. perforation). Even with an Alvarado score of >6, many female cases had an inflamed appendix. Hence, females with a score of >6 maybe advised to undergo USG and if needed laparoscopy. The

implementation of modified Alvarado score is simple cost effective. For the hospital, more important is that the individual patients benefit significantly from important diagnostic accuracy of this common emergency abdominal conditions.
